Questions on Sheet forming are excluded in 2025-2026 A.Y.

Self-assessment questions on Forming by Plastic Deformation

•Indicate when hot forming is preferred in the industrial shaping of metals and alloys

•Explain which phenomena are exploited in hot forming and which are the relevant affecting factors

•Clear up the role played by the strain rate sensitivity coefficient

•Correlate the change of microstructure and mechanical properties during recrystallization of a TMCP

•Discuss why recrystallization is convenient during hot rolling, especially if it is retarded towards low temperature

•Prove why the final grain size after recrystallization decreases with increasing straining

•Elucidate when hot forging is favored over hot rolling in terms of product and mechanical properties requirements

•Compare the residual stress consequence sresulting from small and large rolls during hot rollingof plates

•Compare hot vs. coldrolling in terms of thickness reduction, surface finish and final mechanical properties

•Underline the factors/performances controlled by normal and planar anisotropy in sheet forming
